The Weighted MAX-SAT Problem

Input:	<i>n</i> Boolean variables x_1, \ldots, x_n , a CNF φ =
	$\bigwedge_{j=1}^m C_j$ and a nonnegative weight w_j for each C_j .
Problem:	Find an assignment to x_i -s that maximizes the
	weight of satisfied clauses.

• Obviously NP-hard.

<ロト < 団ト < 団ト < 団ト

• A very straightforawrd randomized approximation algorithm is to set each x_i to true independently with probability 1/2.

(日)

• A very straightforawrd randomized approximation algorithm is to set each x_i to true independently with probability 1/2.

Theorem

Setting each x_i to true with probability 1/2 independently gives a randomized $\frac{1}{2}$ -approximation algorithm for weighted MAX-SAT.

• • = • • = •

Proof

Proof.

Let W be a random variable that is equal to the total weight of the satisfied clauses. Define an indicator random variable Y_j for each clause C_j such that $Y_j = 1$ if and only if C_j is satisfied. Then

$$W = \sum_{j=1}^m w_j Y_j$$

We use OPT to denote value of optimum solution, then

$$E[W] = \sum_{j=1}^{m} w_j E[Y_j] = \sum_{j=1}^{m} w_j \cdot \Pr[\text{clause } C_j \text{ satisfied}]$$

Chihao Zhang (BASICS@SJTU)

(日本) (日本) (日本)

Proof (cont'd)

Since each variable is set to true independently, we have

$$\mathsf{Pr}[\mathsf{clause} \ C_j \ \mathsf{satisfied}] = \left(1 - \left(\frac{1}{2}\right)^{l_j}\right) \geq \frac{1}{2}$$

where l_j is the number of literals in clause C_j . Hence,

$$E[W] \geq \frac{1}{2} \sum_{j=1}^{m} w_j \geq \frac{1}{2} \text{OPT}.$$

Chihao Zhang (BASICS@SJTU)

Approximations for MAX-SAT Problem

Oct. 23, 2012 5 / 16

Proof (cont'd)

Since each variable is set to true independently, we have

$$\mathsf{Pr}[\mathsf{clause} \ C_j \ \mathsf{satisfied}] = \left(1 - \left(\frac{1}{2}\right)^{l_j}\right) \geq \frac{1}{2}$$

where l_j is the number of literals in clause C_j . Hence,

$$E[W] \geq \frac{1}{2} \sum_{j=1}^{m} w_j \geq \frac{1}{2} \text{OPT}.$$

From the analysis, we can see that the performance of the algorithm is better on instances consisting of long clauses.

・ロン ・聞と ・ヨン ・ヨン … ヨ

The previous randomized algorithm can be derandomized. Note that

$$\begin{split} E[W] &= E[W \mid x_1 \leftarrow \texttt{true}] \cdot \Pr[x_1 \leftarrow \texttt{true}] \\ &+ E[W \mid x_1 \leftarrow \texttt{false}] \cdot \Pr[x_1 \leftarrow \texttt{false}] \\ &= \frac{1}{2} (E[W \mid x_1 \leftarrow \texttt{true}] + E[W \mid x_1 \leftarrow \texttt{false}]) \end{split}$$

The previous randomized algorithm can be derandomized. Note that

$$\begin{split} E[W] &= E[W \mid x_1 \leftarrow \texttt{true}] \cdot \Pr[x_1 \leftarrow \texttt{true}] \\ &+ E[W \mid x_1 \leftarrow \texttt{false}] \cdot \Pr[x_1 \leftarrow \texttt{false}] \\ &= \frac{1}{2} (E[W \mid x_1 \leftarrow \texttt{true}] + E[W \mid x_1 \leftarrow \texttt{false}]) \end{split}$$

We set b_1 true if $E[W | x_1 \leftarrow \text{true}] \ge E[W | x_1 \leftarrow \text{false}]$ and set b_1 false otherwise. Let the value of x_1 be b_1 .

The previous randomized algorithm can be derandomized. Note that

$$\begin{split} E[W] &= E[W \mid x_1 \leftarrow \texttt{true}] \cdot \Pr[x_1 \leftarrow \texttt{true}] \\ &+ E[W \mid x_1 \leftarrow \texttt{false}] \cdot \Pr[x_1 \leftarrow \texttt{false}] \\ &= \frac{1}{2} (E[W \mid x_1 \leftarrow \texttt{true}] + E[W \mid x_1 \leftarrow \texttt{false}]) \end{split}$$

We set b_1 true if $E[W | x_1 \leftarrow \text{true}] \ge E[W | x_1 \leftarrow \text{false}]$ and set b_1 false otherwise. Let the value of x_1 be b_1 .

Continue this process until all b_i are found, i.e., all n variables have been set.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

This is a deterministic $\frac{1}{2}$ -approximation algorithm because of the following two facts:

- E[W | x₁ ← b₁,..., x_i ← b_i] can be computed in polynomial time for fixed b₁,..., b_i.
- 2. $E[W \mid x_1 \leftarrow b_1, \dots, x_i \leftarrow b_i, x_{i+1} \leftarrow b_{i+1}] \ge E[W \mid x_1 \leftarrow b_1, \dots, x_i \leftarrow b_i]$ for all *i*.

Flipping biased coins

• Previously, we set each x_i true or false with probability $\frac{1}{2}$ independently. $\frac{1}{2}$ is nothing special here.

Flipping biased coins

- Previously, we set each x_i true or false with probability $\frac{1}{2}$ independently. $\frac{1}{2}$ is nothing special here.
- In the following, we set each x_i true with probability $p \geq \frac{1}{2}$.

Flipping biased coins

- Previously, we set each x_i true or false with probability $\frac{1}{2}$ independently. $\frac{1}{2}$ is nothing special here.
- In the following, we set each x_i true with probability $p \geq \frac{1}{2}$.

We first consider the case that no clause is of the form $C_i = \bar{x}_i$.

- Previously, we set each x_i true or false with probability ¹/₂ independently. ¹/₂ is nothing special here.
- In the following, we set each x_i true with probability $p \ge \frac{1}{2}$.

We first consider the case that no clause is of the form $C_j = \bar{x}_i$.

Lemma

If each x_i is set to true with probability $p \ge 1/2$ independently, then the probability that any given clause is satisfied is at least $\min(p, 1 - p^2)$ for instances with no negated unit clauses.

- Let (y^*, z^*) be an optimal solution of the linear program.
- We set x_i to true with probability y_i^* .
- This can be viewed as flipping different coins for every variable.

Theorem

Randomized rounding gives a randomized $(1 - \frac{1}{e})$ -approximation algorithm for MAX SAT.

Analysis

$$Pr[clause C_j \text{ not satisfied}] = \prod_{i \in P_j} (1 - y_i^*) \prod_{i \in N_j} y_i^*$$

$$\leq \left[\frac{1}{l_j} \left(\sum_{i \in P_j} (1 - y_i^*) + \sum_{i \in N_j} y_i^* \right) \right]^{l_j}$$

$$= \left[1 - \frac{1}{l_j} \left(\sum_{i \in P_j} y_i^* + \sum_{i \in N_j} (1 - y_i^*) \right) \right]^{l_j} \leq \left(1 - \frac{z_j^*}{l_j} \right)$$

◆□▶ ◆□▶ ◆□▶ ◆□▶ □ のへで

Analysis (cont'd)

$$\begin{array}{l} \Pr[\mathsf{clause} \ C_j \ \mathsf{satisfied}] \\ \geq \ 1 - \left(1 - \frac{z_j^*}{l_j}\right)^{l_j} \\ \geq \ \left[1 - \left(1 - \frac{1}{l_j}\right)^{l_j}\right] z_j^* \end{array}$$

Approximations for MAX-SAT Problem

Oct. 23, 2012 14 / 16

(日)(周)(日)(日)(日)(日)(日)

Analysis (cont'd)

Pr[clause C_j satisfied]

$$egin{array}{ll} \geq & 1-\left(1-rac{z_j^*}{l_j}
ight)^{l_j} \ \geq & \left\lceil 1-\left(1-rac{1}{l_j}
ight)^{l_j}
ight
ceil z_j^* \end{array}$$

Jensen's Inequality

Chihao Zhang (BASICS@SJTU)

Approximations for MAX-SAT Problem

Oct. 23, 2012 14 / 16

Analysis (cont'd)

$$\begin{aligned} & \Pr[\text{clause } C_j \text{ satisfied}] \\ \geq & 1 - \left(1 - \frac{z_j^*}{l_j}\right)^{l_j} \\ \geq & \left[1 - \left(1 - \frac{1}{l_j}\right)^{l_j}\right] z_j^* \end{aligned} \end{aligned}$$

Jensen's Inequality

Therefore, we have

$$E[W] = \sum_{j=1}^{m} w_j \Pr[\text{clause } C_j \text{ satisfied}]$$
$$\geq \sum_{j=1}^{m} w_j z_j^* \left[1 - \left(1 - \frac{1}{l_j}\right)^{l_j} \right]$$
$$\geq \left(1 - \frac{1}{e}\right) \cdot \text{OPT}$$
